5 **BACKGROUND OF THE INVENTION**

1. Field of the Invention

sh
AI >
conf
[0002] The present invention relates to a method, and more particularly to a method of IC packing/unpacking for preserving and updating data stored in the IC and the structure thereof. By the packing method, the data stored in the IC is prevented from stealing and copying by others. With such a structure, the operator is able to proceed a data updating process under a safe situation.

2. Description of Related Art

sh
AI >
conf
[0003] It is known in the art that IC is used to store data which includes programs and information. By the programs or information stored in the IC, devices, such as personal computer, is able to process a predetermined function. To enhance the speed and perfection of various functions, designers all try to upgrade the programs they use. Therefore, all kinds of software are developed to the market, and people do benefit from the developed software. However, because the IC itself does not have a defensive system, pirate is able to use the RF frequency generated when data transmitted to copy the program code. In such a way, the designers' perspiration will be wasted and no one wants to spend time to design and develop programs, which is a lost to all industries and a

cont'd

shame to all mankind.

[0004] In order to encourage people to continue to design good and efficient programs, the present invention tends to introduce a method for packing/unpacking IC, such that the data stored in the IC will be protected and piracy action is stopped.

5 [0005] Therefore, it is an objective of the invention to provide a method for IC packing/unpacking and a structure thereof to mitigate and/or obviate the aforementioned problems.

SUMMARY OF THE INVENTION

10 [0006] The main objective of the invention is to provide a method for IC packing/unpacking, with which the programs stored in the IC is protected from being stolen and copied.

[0007] In order to accomplish the above objective, the method comprises the steps of: encasing the printed circuit board having an IC inside with pre-coded plates; generating signals corresponding to the code in the plates; and decoding the coded plates.

15 [0008] In accordance with another aspect of the invention, the structure for accomplishing the above mentioned objective comprises an upper plate having a plurality of coding buttons thereon, a lower plate detachably connected with the upper plate, a printed circuit board (PCB) having an IC inside and sandwiched between the upper plate and the lower plate, a decoder electrically connected with the upper plate and having a
20 plurality of keys protruding therefrom for generating signals corresponding to the coding buttons and a controller electrically connected with the decoder for driving the keys to decode the encased PCB.

[0009] Other objects, advantages and novel features of the invention will become more apparent from the following detailed description when taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

5 [0010] Fig. 1 is a schematic view showing the process of packing a PCB;

[0011] Fig. 2 is a perspective view showing that the PCB is encased by an upper plate and a lower plate and a decoder driven by a controller is able to generate signals for unpacking the encased PCB;

10 [0012] Fig. 3 is a perspective view showing alternative embodiment of the structure of the invention; and

[0013] Fig. 4 is a perspective view showing still alternative embodiment of the structure of the invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENT

15 [0014] Referring to Fig. 1, the method for packing a printed circuit board (PCB) (30) having an IC securely received therein comprises the steps of: encasing the PCB (30) with an upper plate (10) and a lower plate (20), wherein the PCB (30) is sandwiched between the upper plate (10) and the lower plate (20) and then screws (11) are used to secure the connection between the upper/lower plates (10,20) and the PCB (30), coding the plates; generating signals corresponding to the code in the plates; and decoding
20 the coded plates.

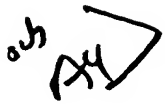

[0015] Referring to Fig. and 2, it is to be noted that the upper plate (10) further has a

A3
contd

trough (12) defined therein and a plurality of coding buttons (13) formed below the
trough (12) for activating the programs stored in the IC in the PCB (30). Furthermore, to
unpack the encased PCB (30), a decoder (40) having a plurality of keys (41)
extending therefrom and a controller (50) electrically connected with the decoder
5 (40) are required. The keys (41) each correspond to one of the coding buttons (13)
and is driven by the controller (50), such that when the unpacking of the encased
PCB (30) is necessary for data storage or program updating, the controller (50),
preferably a personal computer, a laptop computer or a notebook computer, will
generate a signal to activate the decoder (40). The decoder (40), after receiving the
10 signal from the controller (50), will then send out a signal to drive the keys (41) to
"punch" the coding buttons (13) within a time period of 100 ms. The coding
buttons (13) are predetermined such that after receiving the "punch" by the keys
(41), the program stored in the IC will detect whether the sequence of the punch to
the coding buttons (13) is correct. If the result of the detection shows that the
15 sequence of the punch to the coding buttons (13) is not in the predetermined
sequence, then the program stored in the IC will then send out a signal to destroy
every information in the IC. However, if the sequence of the punch to the coding
buttons (13) is in the predetermined sequence, then the program stored in the IC
will then send out a signal to allow unpacking the encased PCB (30).

20 [0016] As described above, when the detection of the punch to the coding
buttons (13) is not in the predetermined sequence, the information stored in the IC
will then be destroyed. The purpose of destroying all the information in the IC is

to prevent intentional piracy or copy.

oh  [0017] Referring to Figs. 3 and 4, another embodiment of maintaining and updating the information stored in the IC is disclosed. When maintaining or updating information in the IC is necessary, an interface (60) (preferably a smart card) enabling to store information therein is used. The interface, after receiving command from the controller (50) to have updated information and/or code therein is then inserted into the trough (12). When the interface (60) is inserted into the trough (12), the program in the IC will automatically match with the pre-stored information and/or code in the interface (60). When the result of the match shows that the code or information in the interface (60) is correct, then the upper and lower plates (10,20) are able to be detached. In other words, if the result of the match shows that the code or information in the interface (60) is incorrect, then detaching the upper and lower plates (10,20) will activate the program in the IC to destroy all the information in the IC.

[0018] Referring back to Fig. 1, it is to be noted that a first connection (14) is formed on the upper plate (10) and a second connection (31) is formed on the PCB (30) to correspond to the first connection (14). When the PCB (30) is encased between the upper plate (10) and the lower plate (20), the first connection (14) engages with the second connection (31), which form a closed loop. The program in the IC will monitor the closed loop at all times, such that when the code in the program is not decoded first and a force is applied to open the closed loop, the

program will automatically destroy all the information in the IC.

[0019] From the foregoing description, it is concluded that the method for unpacking the encased IC comprises the steps of: coding an interface; matching the coded interface with the code in the IC; and generating signals to allow
5 maintenance to the information in the IC or destroy all the information in the IC.

[0020] It is to be understood, however, that even though numerous characteristics and advantages of the present invention have been set forth in the foregoing description, together with details of the structure and function of the invention, the disclosure is illustrative only, and changes may be made in detail,
10 especially in matters of shape, size, and arrangement of parts within the principles of the invention to the full extent indicated by the broad general meaning of the terms in which the appended claims are expressed.
